Modern microprocessors use a system of registers, in combination with various built-in instructions, to manage computation and memory operations. Each of these registers may be set to different values, depending on the instruction currently executing. In a software program, instructions may be pipelined, which means multiple instructions are being executed simultaneously. Because it is difficult to know the exact state of each register when an instruction is about to be executed, some modern microprocessors include at least one “shadow register” or “shadow register file,” which is used by the microprocessor to store information about a currently executing instruction. Shadow registers are not actually part of the microprocessor but rather are a separate component to the microprocessor. The shadow register may provide some indication of what state the microprocessor should set a register to when the instruction is executed. The shadow register may also contain the current program counter value, which indicates the address of the currently executing instruction. A shadow register may be implemented as a separate chip, or it may be implemented as a portion of the microprocessor that is programmable so that it can be customized to store different information. Shadow registers generally are structured to be as fast as possible, since they are not included in the actual microprocessor, and, thus, shadow registers tend to be smaller than some registers of the microprocessor. In some embodiments, the shadow registers are used to hold a state of the microprocessor, such as certain register values or other information. However, in these embodiments, the shadow registers store only a static state. In other embodiments, the shadow registers are used to hold the current state of the microprocessor, such as the values of registers and instructions. These are referred to as dynamic shadow registers. This also means that some shadow registers are static, while others are dynamic. In some embodiments, there are several shadow registers that can be used for various purposes. For example, there may be static shadow registers that are used to hold values that are not changed in a predictable way. There may also be dynamic shadow registers that can be used to hold any other register values that 2d92ce491b
