Category:Living people Category:1972 birthsQ: How do I avoid recursion here? My goal is to count the number of solutions to a equation, with the constraints that they are greater than 1, between 0 and 10, and one of them is odd. The equation looks like this: where: A = 1 B = even number from 1 to 10 inclusive C = odd number from 1 to 10 inclusive The count function takes in a list of variables, or "vars", and then the equation. from itertools import product def count\_solution(vars, eq): n = 0 for solution in product(vars, repeat=len(vars)): if all(solution > 1 for s in solution): for c in solution: if c % 2 == 1: n += 1 return n a = 2 b = 1 c = 3 print(count\_solution([a, b, c], (a+b-c)\*\*2 - (a-b)\*\*2 - c\*\*2)) Which I'm trying to interpret as: Is this the correct way to count the number of solutions? How can I avoid the recursion? Is there a better way? A: A more explicit solution: from itertools import product def count\_solution(vars, eq): """ Returns the number of solutions to the equation `vars[0] + vars[1] = vars[2]` where `vars[0] > 1`, `vars[1] > 0`, and `vars[2] % 2 == 1`. """ num\_sols = sum(1 for \_ in product(range(len(vars)), repeat=len(vars)) if all(vars[0] > 1 for \_ in product
