No. 5,344,454. With these implants, anchoring between the cone and the head takes place, with the result that the implant can not come into optimal contact with the conical portion of the vertebral body. This may lead to the formation of fistulas. To avoid the disadvantages of these hollow double-tapered implants, implant systems are known in which the implant has a conical portion in which a supporting element (for example a head) is held, and a cylindrical portion with a cone-shaped threaded section for anchoring in the vertebral body. In German Utility Model No. DE 296 20 605 U1 and German Patent No. DE 40 16 945 C1, the head is designed as a partially cylindrical ball which is pressed into the conical portion. The two surfaces of the conical portion have a helical threading, so that the supporting element is wedged with the aid of the conical portion. In the other cases, the conical portion is not connected to the cylindrical portion. In this case, the conical portion has a helical threading, which is inserted into a screw thread in the cylindrical portion. Here, however, the conical portion can not be removed from the cylindrical portion without the aid of a special tool. The disadvantage of the helical threading is that the tensile forces in the conical portion of the implant are partly transferred to the cylindrical portion. This may lead to the formation of fistulas. German Patent No. DE 36
