From the Node.js API Reference docs: // list instances for the given name TCPInstance.listInstances([name]) List the instances of a given name. It says that: This is a wrapper for http.get in a way that allows to add multiple concurrent TCP connections. This can be used to overcome the problem with HTTP2 where it is not possible to create more than 1 connection per host. I have little knowledge about networking but I think TCP connections are generally uni-directional. So why is the API designed to have more than one TCP connection on a port? Does this help something? A: The short answer is that TCP is a protocol that is reliable, while UDP is unreliable. If TCP connections (or "datagrams" as they are sometimes called) are lost or are otherwise not transmitted in the expected way, it makes it difficult to recover those connections. This is the core reason why UDP is not used for TCP traffic. If you send a TCP message over UDP, 2d92ce491b
