Since HTML is a tag-based language, it is possible for a developer to use a particular tag in a variety of ways. For example, if someone wanted to have text appear in bold, they might use a tag for bold ( ) and another tag for italicized ( ), and add both tags to the paragraph. In this way, it is possible for someone to make everything within a paragraph appear in bold, without actually using a tag for bold. However, as I have mentioned earlier, we must be clear on what is an algorithm, and what is a program. Thus, a compiler, which translates a program into an executable format, might not have the ability to do any such thing. The original instruction set of all the CPUs and computer chips that you use today is based on binary numbering, where every number is represented as 0s and 1s. Thus, a binary number 1010 is represented as 10001; 1 1010 is represented as 1100100. The program that we write using assembly language can be mapped one-to-one to the binary numbers in this way. The operation represented in binary
