The present invention relates generally to frequency selective surface assemblies and, more particularly, to a technique for using a single layer frequency selective surface to simultaneously suppress a broad band of undesired frequencies and increase the selectivity of the frequency selective surface to a particular desired frequency. The invention is particularly applicable to suppressing undesirable radiation from a horn antenna or other horn-shaped antenna, but it will be

appreciated by those skilled in the art that the invention has broader applications and may be adapted for use with a variety of other types of antennas. The structure of a typical horn antenna is schematically illustrated in FIG. 1. As shown therein, a horn antenna 10 is a horn-shaped waveguide or conduit which couples electromagnetic signals from a high-power source, such as a transmission line, to a directional radiating element 11, such as a loop antenna or a horn-shaped radiation aperture. The horn is a member which has been shaped to increase its radiation efficiency. As a high-power wave propagates through horn 10 it reaches

transition region 12 at a first turning point where the wave is substantially orthogonal to a longitudinal axis 13 and continues to propagate into second transition region 14 at a second turning point where the wave is substantially parallel to longitudinal axis 13. Because horn 10 is an elongated structure, the frequency distribution of electromagnetic energy radiated by a horn antenna 10 is influenced by the conductance of the horn. The attenuation of the radiating aperture at a given frequency is a function of both the resistivity and conductance of the horn at the frequency of the radiation. It has been previously found that good

radiation characteristics can be obtained with a horn made of a conductance layer which exhibits an extreme value of conductance at a particular frequency. This extreme value of conductance is a function of the shape and size of the aperture forming the horn. As the current carrying area of the horn is increased, the frequency of the maximum value of the conductance of the horn decreases and the radiation pattern is changed. A frequency selective surface (FSS) may be fabricated by the same process as used to construct a horn antenna 10. FSS 15 of FIG. 1 functions as a frequency selective surface for horn antenna 10. As a representative example,

the dimensions of horn antenna 10 were
adjusted to achieve the maximum
